What is a ventilation system in an underground mine?

The purpose of the ventilation system in an underground mine is to provide and drain clean air into the mine for breathing and comfort of mine workers. Based on the Ventilation Design Criteria used by PTFI, the minimum airflow level required for every mine worker is 0.033 m<sup>3</sup> /s /worker.

What is intelligent construction of mine ventilation?

Many experts and scholars have made efforts for the intelligent construction of mine ventilation. Professor Zhang Qinghua pointed out that intelligent perception, intelligent decision-making and intelligent control are the research and development directions for realizing intelligent ventilation .

What are the components of a mine ventilation system?

The main components of a mine ventilation system are intake, working, and exhaust. Intake is a tunnel and wells system where air flows from the surface into the mine. The purpose of the ventilation system in an underground mine is to provide and drain clean air into the mine for breathing and comfort of mine workers.

Is the mine ventilation system open or semi-manual?

At present, the mine ventilation system is still in the artificial or semi-manual stage, which is far from the open and intelligent system. It is imperative to break through the common problems of the industry and improve the intelligent level of mine ventilation.

What is a mine ventilation design?

Recently, research on mine ventilation has focused on analytical methodology [4, 5] and optimization [6, 7]. Mine ventilation design includes estimates of air quantity required by each branch, ventilation network analysis, and the development of various measures to satisfy such requirements.

How a mine is ventilated?

Current mining and development level is at a depth of 1507 meters and both ore and waste rock is hoisted to the surface. Ventilation is performed mechanically with no complementing air-conditioning. Mine ventilation is in every underground mine a crucial process to ensure mine safety as well as acceptable working conditions.

According to the layout of the intake air shaft and the upcast air shaft, the mine ventilation system can be divided into three types: (1) centralized ventilation: the ventilation mode is that the intake and the upcast air shafts are arranged in the center of the mining field and that the airflow route is in a switch-back type; (2) radial ventilation: the ventilation mode is that the ...

# Design specification for coal mine ventilation shaft energy storage system

Specific conditions of underground coal mines at great depth, such as high temperatures, high rates of methane inflow and natural ventilation pressure provide considerable challenges for the reliable design of appropriate mine ventilation systems. For decades coal mining in Germany has coped with these extreme circumstances.

ventilation requirements of the mine production plan. THE CONVENTIONAL VENTILATION PLANNING PROCESS. The design process of a mine ventilation plan requires a number of assumptions to determine the airflow volume required, and the factors causing and resisting this flow underground, allowing a ventilation design to be completed.

Some particular spaces in coal mines, such as vertical shafts, can also be used. Therefore, the current scenarios mentioned above for hard rock caverns may not be the best choice for coal mines.
