Energy density corresponds to the energy accumulated in a unit volume or mass, taking into account dimensions of electrochemical energy storage system and its ability to store large amount of energy. On the other hand power density indicates how an electrochemical energy storage system is suitable for fast charging and discharging processes.

With a high surface area, shorter ion diffusion pathways, and high conductivity, MXenes enhance the energy storage characteristics of a supercapacitor. The key to high rate pseudocapacitive energy storage in MXene electrodes is the hydrophilicity of MXenes combined with their metallic conductivity and surface redox reactions.

So, ESS is required to become a hybrid energy storage system (HESS) and it helps to optimize the balanced energy storage system after combining the complementary characteristics of two or more ESS. Hence, HESS has been developed and helps to combine the output power of two or more energy storage systems (Demir-Cakan et al., 2013).

thermal energy (in furnaces or combustion chambers), then into mechanical energy, and finally into electric power by means of generators. In the case of electrochemical power sources, this multistep process is replaced by one step only. As a consequence, electrochemical systems show some advantages such as high energy efficiency.
