Which method is used to initiate thermal runaway?

The methodology used for initiating thermal runaway pursuant to cell level test shall be used to initiate thermal runaway within the module. Thermal runaway methodology for module level test: The propensity of the module to exhibit thermal runaway was demonstrated by heating the cell with externally applied heaters.

What is thermal runaway method for module level test?

Thermal runaway methodology for module level test: The propensity of the module to exhibit thermal runaway was demonstrated by heating the cell with externally applied heaters. With a surface heating rate of 4°C (7.2°F) to 7°C (12.6°F) per minute until cell thermal runaway occurs within the test module.

Why is thermal runaway a concern for ESS installations?

The greatest concern for ESS installations was thermal runaway in a battery module that could propagate to a significant fire or explosion, especially since there were no proven methods for controlling or suppressing a fire or mitigating a potential explosion.

What is a thermal runaway rate?

With a surface heating rate of 4°C (7.2°F) to 7°C (12.6°F) per minute until cell thermal runaway occurs within the test module. The number of cells within the module that are forced into thermal runaway can be one or multiple cells, and is dependent upon the energy contained within the individual cells.

How to measure chemical heat release rate in thermal runaway?

The chemical heat release rate of the module in thermal runaway shall be measured with oxygen consumption calorimetry. The chemical heat release rate shall be measured for the duration of the test.

How is thermal runaway verified?

With reference to 8.2.5, occurrence of thermal runaway shall be verified by sustained temperature above the cell surface temperature at the onset of thermal runaway, as determined in Section 7. The module shall be placed on top of a noncombustible horizontal surface with the module orientation representative of its intended final installation. 3.

The UL 9540A test standard provides a systematic evaluation of thermal runaway and propagation in energy storage system at cell, module, unit, and installation levels. The data from this testing may be used to design fire and explosion protection systems needed for safe siting and installation of ESS.

To prevent thermal runaway propagation, the following recommendations were made by Feng et al. [87]: (i) raising the thermal runaway temperature's onset to above 470 °C (ii) lowering the electric energy released during internal short circuits (iii) enhancing heat dissipation by raising the heat dissipation coefficient
