What are wound rotor wind generators?

Wound rotor wind generators have two main categories. They could be either of typical synchronous generators (Fig. 3) or induction generators (WRIG) which fall in two subcategories, dynamic slip-controlled (Fig. 4) and doubly fed induction generators (Fig. 5).

What is a wound rotor induction generator?

A wound rotor induction generator (WRIG) with variable resistance is employed in this configuration. Power converter is used to adjust the variable resistance as shown in Fig. 2 (b). The rating of power converter is 10% of the rated power of generator. Additionally, a reactive power control, soft starter, and gearbox are essential for this system.

What is a generator rotor?

The generator rotor represents an excellent combination of electrical, mechanical and manufacturing skills in which the field coils are well insulated, supported and ventilated in a compound structure rotating at very high speed (typically 1800 or 3600 rpm).

Can a generator rotor be converted to a direct cooled winding?

Depending on the design of the rotor, in some cases it is possible to convert to a direct-cooled winding. Converting involves machining subslots in the rotor forging below the coil slots. Because of rotor geometry and size, this modification is not possible on all rotors. Q. Is there asbestos in generator rotor insulation and blocking materials?

How many RPM is a generator rotor?

A common ratio is about 90:1, with a rate 16.7 rpm input from the rotor to 1,500 rpm output for the generator. The multiple wheels and bearings in a gearbox suffer tremendous stress because of wind turbulence and any defect in a single component can bring the turbine to a halt.

What causes a generator rotor to degrade?

One component of the generator that is typically refurbished, upgraded or updated is the generator rotor (field). Degradation of the generator field can be caused by a number of factors, including a breakdown in insulation due to time and temperature and mechanical wear.
