What is a shaft generator?

Installing a shaft generator on board a vessel. The shaft generator enables production of electric power by the engine that has a low specific fuel consumption. In addition, the lower number of running hours of the gensets reduces maintenance and expenses for spare parts. In the early 2000s, shaft generators were more

What are the benefits of a shaft generator?

Converts shaftline into electrical energy. This can power onboard systems or be stored to supplement engine power later. Among the benefits of this approach are: Fuel efficiency: Shaft generators on main engines reduce use of auxiliary engines for generating electricity, leading to improved fuel efficiency.

Where is a shaft generator installed in a diesel engine?

The shaft generator is installed in the shaft line between the low-speed main diesel engine and the propeller. This configuration has a large air gap between the stator and the rotor, and without additional bearings has proven very successful as the most frequently used configuration.

How does a shaft generator work on a ship?

Shaft generators on board ships are driven by the main engine to supply power to the mains. The mains have to be supplied with constant voltage and frequency by the shaft generator whilst the speed of the main engine changes, i.e. when the vessel travels at different speeds or if the propeller speed strongly varies in heavy seas.

How does a diesel engine shaft generator work?

This is the usual and appropriate configuration for medium-speed main diesel engines. The shaft generator is operated via a tunnel gear unit installed in the shaft line between the low-speed main diesel engine and the propeller.

How does a shaft generator affect engine speed?

Engine speed under the added resistance. The power taken out via a shaft generator adds to the power required for driving the propeller. As resistance increases on the hull, e.g., when the sea state develops, there comes a point where load must be transferred from the shaft generator to the gensets.

**Demand Fluctuations:** Fluctuations in global trade, consumer demand, and maritime activities during the pandemic impact market demand for new vessels, ship retrofits, and onboard equipment such as marine shaft generators, resulting in reduced order intake, project cancellations, and deferred investments in energy-efficient propulsion systems.

Most of the components of a dam-free micro-hydropower system are identical to dam-associated systems and include intake and screen, penstock, turbine, generator and interconnection. ... The turbine's job is to ...

Shaft generators are an effective measure to lower emissions and fuel consumption. Traditionally the standard approach is to mount such a system in the stern at the propeller shaft. As this is not possible for all ships, RENK is ...

Intake - Gates on the dam open and gravity pulls the water through the penstock, a pipeline that leads to the turbine. Water builds up pressure as it flows through this pipe. Turbine - The water strikes and turns the large blades of a turbine, ...

Leading Shaft Generator Solutions Towards Zero Emission Shipping Our solutions build on widely proven technologies and are applicable for most ship types and propulsion machinery (e.g. low speed direct driven propeller with 2-stroke Main Engine, or medium speed reduction gear driven propeller with 4-stroke Main Engine).

intake design include the following. Toxic Stack Exhausts. Boilers, emergency generators, and laboratory fume hoods are some sources that can seriously affect building indoor air quality because of toxic air pollutants. These sources, especially diesel-fueled emergency generators, can also produce strong odors that may require administrative ...

Good shaft generators start to work at best at 40 % SMCR power, but with limited efficiency. As the IFPS is directly connected to the crankshaft and by using a single-gear stage, the generators benefit from much higher RPMs.

The existing intermediate shaft and bearings were replaced to accommodate the increased weight. Overall, the company has successfully delivered more than 650 shaft generator systems and has over 50 years of experience in this field. The "Berge Toubkal" retrofit was completed in Q4 2022, following ten months of preparation time.

The shaft power plant is designed for a developed flow of 1.5 m<sup>3</sup>/s (accurate discharge measurement by means of an upstream Rehbock-flume) and a ... outflow) confirm the selected hydraulic intake concept. Since the generator is also in the water body and is thus optimally cooled, there is an additional positive influence on the efficiency.

Why shaft generators? Shaft generators were first introduced in the 1960s. Their main advantage is the better fuel economy of a two-stroke engine technology compared to four-stroke technology. When electric power is produced with a slow-speed main engine instead of medium- or high-speed gensets, this results in significant fuel savings.

In most hydro turbine generators, the intake shaft is a pipe that connects the water into the turbine and allows it to flow through the system and into the turbine blades. The intake shaft is designed to help water flow towards the blades of the turbine with a certain amount of force, depending on the volume and head height of the water.
