If you compare the current reading to the solar panel's maximum output power (the I_{mp} on the back of the panel), you'll see how close your solar panel is to its maximum capacity. In my case, my solar panel's I_{mp} is 6.26. I'm measuring a current of 4.46A. While this may seem like a bad idea, it's actually not that far off.

The monocrystalline silicon in the solar panel is doped with impurities such as boron and phosphorus to create a p-n junction, which is the boundary between the positively charged (p-type) and negatively charged (n-type) regions of the silicon. This junction is what enables the solar panel to convert sunlight into electricity.
