

Photovoltaic panel load-bearing capacity test method

Why does a PV module need a snow load test?

As a result, the lower part of the module will need to withstand greater stress. Additionally, ice may accumulate between the frame and the glass thus causing further stress to the PV module. With IEC 62938, non-uniform snow load tests simulate failure types similar to those in field conditions and thus reflect real snow impact to the PV modules.

What is the standard test method for reporting photovoltaic non-concentrator system performance?

One popular test is ASTM 2848-13 "Standard Test Method for Reporting Photovoltaic Non-Concentrator System Performance". The goal of this test is to compare the ratio of a modeled system vs the actual system performance, and the system should perform the same as the model, minus some uncertainty.

How does a PV module test work?

Specifically, the test determines the load limit of the PV module. Six modules are used with five modules tested to their failure limit while the sixth module is stressed with approximately 63% of the mean load of the five modules beyond their failure limit.

What are the performance PV standards?

The performance PV standards described in this article, namely IEC 61215 (Ed. 2 - 2005) and IEC 61646 (Ed. 2 - 2008), set specific test sequences, conditions and requirements for the design qualification of a PV module.

What is a mechanical load test?

This loading test is to investigate the ability of the module to withstand wind, snow, static or ice loads. Mechanical load comes after Damp Heat and therefore done on a sample that has undergone a severe environmental stress.

Why do PV plants need double horizontal load tests?

When PV plants are designed with fixed type panels, the lateral load is less limiting and the number of this type of tests could be reduced. When conducting double horizontal load tests, the reaction equipment will need to be duplicated. This reduces the shear stress and maintains the bending moment at the base.

Plate load test is a field test which is commonly adopted to determine the bearing capacity and settlement of soil under a given condition of loading. In this test a square or circular rigid plate of standard dimension (generally 300 mm² for square or 300 mm dia for circular) is placed at foundation level and load is applied in increments.
